

PyConES 2026 runs on coffee. Lots of coffee.

Right next to the main hall, the organisers set up **PyCafé**, a tiny stand with one very tired barista and one very loud espresso machine. Every time someone orders a coffee, the barista writes their name on a list. No names on cups, no loyalty cards, just a list that keeps growing all weekend.

On Sunday night, someone from the organising team has a brilliant idea:

"Let's give a prize to the person who drank the most coffee!"

The barista slides the list across the counter. It has **thousands** of lines, and the same names show up again and again.

"Counting them by hand would take longer than the conference itself."

You already know who they are going to ask. The editor is open. The espresso machine is still screaming.

Problem Statement

You are given the list of names written by the barista, one name per coffee ordered.

Find the person who ordered the **most coffees** and print their name and how many coffees they had.

If several people are tied for the most coffees, print the one whose name comes **first in alphabetical order**.

Names are compared as plain text, so **dev10** comes before **dev2**.

Input Format

The first line contains an integer **n**, the number of coffees ordered.

Each of the next **n** lines contains one name.

Constraints

- $1 \leq n \leq 100,000$
- Each name has between **1** and **20** characters.
- Names contain only lowercase English letters and digits.

Output Format

A single line with the winner's name and their number of coffees, separated by a space.

Sample Input 0

```
8
lucia
marco
lucia
```

```
ana  
marco  
lucia  
ana  
marco
```

Sample Output 0

```
lucia 3
```

Explanation 0

lucia and **marco** each ordered 3 coffees and **ana** ordered 2. Since **lucia** and **marco** are tied, the winner is **lucia**, because it comes first alphabetically.
